

Chapter 7: Lists & Tuples

Python provides compound data structures to store collections of items within a single variable. 1.

Lists: - Defined using square brackets []. - Mutable (elements can be modified, appended, or removed after creation). - Supports indexing, slicing, and methods like append(), pop(), and sort(). 2. Tuples: -

Defined using parentheses (). - Immutable (cannot be changed, added to, or altered once instantiated). - Faster performance than lists due to fixed memory allocation.
